Keywords: unknown locations, hypnotic induction, out-of-body-consciousness, hypnosis, remote viewing

Advanced Research in Psychology

Four participants, chosen for their experience in reaching an Out-of-Body state of consciousness via hypnotic induction, were asked to describe five different and unknown locations, at first using Remote Viewing conditions in an ordinary state of consciousness and then again using Remote Viewing in Out-of-Body state of consciousness. According to an assessment by two independent judges, the average percentages of information obtained in Remote Viewing were 55% for those correct and 35% for those wrong, while in Out-of-Body they were 54% and 35% respectively. The average percentage of identical information to both conditions was 14%. Furthermore, three out of four participants obtained a higher percentage of correct answers and a lower percentage of incorrect answers in the OB-RV condition. This study illustrates the possibility of also using Remote Viewing in an Out-of-Body state of consciousness that is induced and controlled via hypnosis to obtain accurate information about unknown locations in an unconventional way.

1 Introduction

The main research hypothesis of this study, was to confirm if Remote Viewing (RV) in an hypnotically-induced Out-of-Body (OB) condition is more accurate in identifying target features than RV in an ordinary state of consciousness. The ability to obtain information from a distance about persons, events, physical places, objects and various types of buildings in an ordinary state of consciousness is commonly defined as RV. A comprehensive description of its characteristics, origins, techniques and range of applications is given by Stephan Schwartz (2017) and Russell Targ (2019).

In brief, this perception technique – in use since the 1960s – consists of asking someone to describe a specific and unknown target without any conventional means of acquiring information about the target itself.

Although the state of consciousness of people using this technique seems to resemble an ordinary wakeful state, the ability to differentiate the information about a specific target from that generated by normal mental activity, for example expected or inferred information, requires a special ability to filter this last one in order to identify the target's details, given that they don't travel through the sense organs.

The following is an example of how Joseph McMoneagle, one of the leading experts in RV, describes his mental state:

"I find that when things work best for me is when I've been able to ample up my awareness about what's going on around me within specific circumstances. ... when I then verbalize what is going on inside me, my body, my head, my mind and physical properties, I have to in some way translate this into something understandable to another human being... I got a tremendous dose of impressions which contained a lot of noise, and a myriad of visual flashes, which were all nonsensical. In my efforts to try and decipher what was happening, I arrived at a purely hypothetical drawing of what tasted or felt the best to me... If anything, I'd have to say that I've learned to meditatively empty my mind and concentrate on choosing those things I need to pay atten-

tion to the most, and then being able to statistically derive an answer as to what I'm supposed to say" (Joe McMoneagle, personal communication).

From this short description it is clear that the effective use of RV requires having or reaching a specific mental state which is different to the ordinary waking state.

Experimental evidence obtained under strictly controlled conditions to eliminate any possibility of fraud or conventional access to information, supports the authenticity of this mental ability. The most recent quantitative synthesis of all studies conducted up to 2014, provided by Baptista, Derakhshani & Tressoldi (2015), highlights an average accuracy percentage of 36.6% compared to an average percentage of 25% for random selections.

Even if an accuracy of 36.6% seems far from an ideal 100%, under certain conditions and with very gifted participants promising practical results have been obtained in the recovery of archaeological finds (e.g. Schwartz et al., 2000), in predicting financial events (e.g. Smith et al., 2014), and in intelligence activities (e.g. Marwaha & May, 2017; Targ, 2019).

1.1 Remote Viewing with Out-of-Body Consciousness

In an OB state like that of induced with hypnotic suggestions is it possible to obtain information comparable to, or even better than, that obtained using RV?

Given that the OB state (see Alvarado, 2015, for a complete description of this unusual state of consciousness) has the peculiar trait of experiencing one's centre of consciousness as detached from the physical body, and therefore also from all sense organs, from the 1970s onwards some researchers have attempted to confirm the possibility of inducing a controlled state of OB, and then asking participants to move their centre of consciousness to gather information about a specific target. The pioneers of this research path were Charles Tart and John Palmer.

For example, Palmer and Vassar (1974) attempted to induce OB experiences (OBes) by progressive muscular relaxation techniques and audio-visual stimulation and then in-

structed their participants to travel to another room and to try to see a target. However, the subjects who reported OBEs obtained scores lower than would be obtained by chance alone. Palmer (1978), in summarizing his experiments, did not find support for the hypothesis that scores for subjects who report OBEs were statistically above chance and statistically higher than those of subjects who did not report OBEs.

A study in which OB was induced using hypnosis is described in Tart (1998). Seven participants, who were all in the upper 10% of the hypnotic susceptibility range, received a suggestion after they reached a very deep hypnotic state to move their consciousness to a distant locked laboratory and to carefully observe some specific target objects. However, none of their reports matched the characteristics of the targets and no formal analysis was completed.

Tressoldi & Del Prete (2007) aimed at comparing the differences between hypnosis with an OB versus ordinary (no OB) hypnosis, with respect to the capacity to perceive distant pictures outside of the sensory visual range. In this study no differences were found between the two hypnotic inductions. In both conditions, participants obtained an overall accuracy of 3.7% above chance.

Tressoldi et al. (2014) tried to replicate and improve the previous study of Tressoldi & Del Prete (2007). Five participants selected for their experience with hypnotic inductions were induced into an OB and were requested to verbally describe six selected images placed in two different rooms located hundreds of kilometres from the place where they were under hypnosis. On average, the participants correctly identified 46.7% of the images, compared to a probability of 25% expected due to chance. However, this study did not have a control condition with which to compare the results obtained in the OB.

This study may be considered a conceptual replication of that of Tressoldi et al (2014).

The main differences are:

- in order to make it more interesting for the participants and the task more ecological, the targets were two churches, a museum and two historical buildings;
- all participants were asked to describe these targets at first in the RV condition, followed by the RV in the OB state (OB-RV).

2 Materials and Methods

2.1 Participants

The participants were four women with an average age of 54, ranging from 42 to 69, selected from the group of Evan-Lab candidates for their experience with the state of consciousness in OB induced via hypnotic suggestion. The experience varied from a minimum of 12 to a maximum of 37 sessions all conducted by the same hypnotist. However, none of them had ever experienced obtaining information from physical locations using either RV or OB-RV techniques. The hypnotist, LP, has been practicing hypnosis for research purposes for over 20 years and also has more than 10 years' experience in inducing non-ordinary states of consciousness.

The study was reviewed and approved by the Ethical Committee of Psychological Research of Padova University. Prot. n. 2058. The participants provided their written informed consent to participate in this study.

2.2 Procedure

On the agreed day, each participant individually carried

out an RV session followed by an OB-RV induced via hypnotic suggestion, attempting to describe as accurately as possible the targets proposed by the hypnotist. Neither the hypnotist nor the participants had ever seen or visited the targets or the cities in which they were located.

When a participant signaled that she was ready, the hypnotist gave the following instructions: *"Now concentrate and try to provide as much information as you can get on [target name] located in Treviso (city in Italy where all targets were located).*

During the RV session the hypnotist's only task was to assist the participant to accurately describe all of the target's different features and find as many of them as possible.

At the end of the RV session, when the participant indicated being ready, the OB induction via hypnotic suggestion procedure began as described by Pederzoli & Tressoldi (2018). Given that the participants were very familiar with this technique, the time required to subjectively reach the OB state varied from 4 minutes to a maximum of 7 minutes. When the participant replied in the affirmative to the question *"Are you in an OB state?"*, she was asked to describe as accurately and completely as possible the same target as in the RV session.

In this session the hypnotist's task was identical to that in the RV session.

The decision to not alternate the order of RV and OB-RV sessions was made based on the hypothesis that in the latter it was easier to obtain more target information and thus it could influence the performance in RV if it was done immediately after.

All the sessions were audio-recorded.

2.3 Targets

The targets were two churches (an old one and a contemporary one), a modern museum and two historical monuments in the city of Treviso, located in Italy's north-east, near Venice.

This city and the targets within it were chosen because firstly, the hypnotist and participants were unfamiliar with it, and secondly, it was physically accessible so that afterwards the features described by participants could be checked and photos taken for data analyses. Photos of the five targets are available at <https://doi.org/10.6084/m9.figshare.12192474.v3>.

2.4 Data analyses

The audio recordings of each session were sent to co-author PT, whose task was to compile a written list of every item of information provided by the four participants for each of the five targets. The only information not included were subjective opinions, such as: *"There's a lovely entrance door,"* and anything that could not be verified, such as: *"It's a place where initiation rites were held."*

2.5 Scoring

Each item of information provided by each participant was marked as either correct, partially correct (and reasons why), or wrong. Information which was totally correct or wrong was given a score of 1 point, and those partially correct were given half a point. Finally, all the points for these three categories were added for each target.

The same task was carried out by a second judge using the available photos, with no way of knowing if they refer

Table 1: Example of evaluation relative to Target SV

Information	YES/ NO	PARTIAL
A square-shaped bell tower no taller than the church		Squared, but higher than the church
Ochre-coloured façade	YES	
Large door in the middle of the entrance	YES	
A Romanic-type arch with sculptures (the Good Shepherd with sheep)		Not a Romanic-style arch, and sculpture is not of the Good Shepherd

Table 2: Descriptive and inferential statistics of the number of information obtained in RV and in OB-RV and of the percentage of similar information in both conditions.

	info in RV	info in OB-RV	% Identical info
Mean	10.5	12.6	.14

to RV or OB-RV, such as the example shown in Table 1, with respect to target 'SV' presented in Figure 1.

Lists of the information relative to all 20 RV and 20 OB-RV sessions, with their associated score given by two judges, are available at <https://doi.org/10.6084/m9.figshare.12192474.v3> together with photos of the targets to allow independent verification.

3 Results

The descriptive and inferential statistics relative to the information obtained from the 20 RV and 20 OB-RV sessions are presented in Table 2, together with the percentage of identical information.

3.1 Comment

In the OB-RV condition, participants provided around

Table 3: Descriptive and inferential statistics of the comparison between correct and wrong information obtained in RV and in OB-RV.

	Correct info in RV	Wrong info in RV	% Corr. info in RV	% Wrong info in RV	Correct info in OB-RV	Wrong info in OB-RV	% Corr info in OB-RV	% Wrong info in OB-RV
Mean	5.5	4.05	.54	.36	6.9	4.2	.55	.34
SD	2.3	2.3	.10	.11	2.7	1.8	.09	.10
<i>ESd</i>		.98		.86		.99		1.08
<i>p</i> *		.0001		.0001		.0001		.0001

ESd = Cohen's d effect size; *p** = paired t-test *p* value

Table 4: Descriptive and inferential statistics related to the comparison between correct and wrong information obtained in the RV and in the OB-RV conditions

	Correct info in RV	Correct info in OB-RV	Wrong info in RV	Wrong info in OB-RV	% Corr info in RV	% Corr info in OB-RV	% Wrong info in RV	% Wrong info in OB-RV
Mean	5.5	6.9	4.05	4.2	.54	.55	.36	.34
SD	2.3	2.7	2.3	1.9	.10	.09	.11	.10
<i>ESd</i>		.50		.09		.05		.16
<i>p</i> *		.04		.69		.81		.47

two information more than in the RV one, but the most interesting finding is that only 14% of this information is identical to both the RV and OB-RV conditions (e.g. "Access stairway with 4 steps"; target LC; participant D).

Another relevant finding is that the participants very often obtained different information from the identical targets. The total number of different information is: SP = 77; SV = 84; LC = 89; ME = 66; PSQ = 42.

3.2 Interjudges agreement

The average Pearson correlation between the scores of the two judges was .71; 95% CI: .39 - .87; ranging from .84 for correct information in OB-RV condition to .44 for wrong information in the OB-RV condition.

The scoring of both judges is presented in the Supplementary Material section. It was therefore decided to use the average score given by the two judges to compare the descriptions between the RV and OB-RV conditions.

3.3 Comparison between correct and wrong information

Comparisons between correct and wrong information of all participants in the RV and OB-RV conditions are shown in Table 3 and Figures 2, 3, 4 and 5. Individual performances of participants are presented in Table S2 in the Supplementary Material.

3.4 Comment

The differences between the number and the percentage of correct and wrong information both in RV and OB-RV

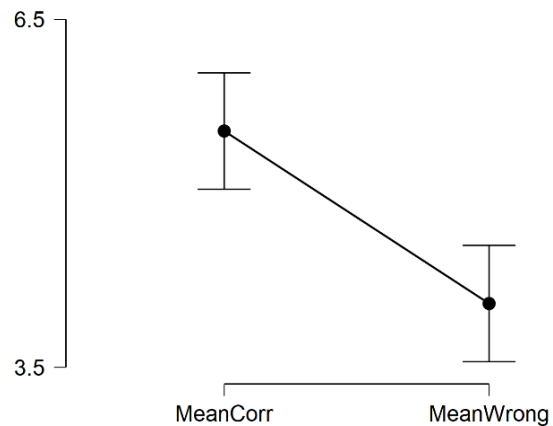

Figure 2: Means and 95% confidence intervals related to the comparison between the number of correct and wrong information in the RV condition.

clearly show the correct ones to be greater.

In percentage terms, this difference is around 20% in both conditions. The total of percentages of correct and wrong answers is not equal to 100 because partially correct answers were given a score of half a point.

3.5 Comparison between RV and OB-RV performances

Table 4 shows this comparison.

3.6 Comment

The only difference between RV and OB-RV conditions is in the raw number of correct information, resulting in an average of one more information in the OB-RV condition.

However, if the individual performance of the four participants, presented in Table S2 in the Supplementary Material, is analyzed, it can be observed that three out of four participants had a higher percentage of correct answers and a lower percentage of incorrect answers in the OB-RV condition.

4 Discussion

The purpose of this study was to compare the ability to identify and describe physical targets, from a distance, in the RV and OB-RV states of consciousness.

The results clearly demonstrate that in both conditions, the amount of correct information is clearly greater than wrong information, with a difference of around 20%. The only difference in performance between the two is in the number of correct information, which is slightly greater in the OB-RV condition.

An interesting finding from this comparison is that the percentage of identical information to both the RV and OB-RV is only around 14%.

This fact not only suggests that in these two states of consciousness the participants were able to gather different information, but also that they did not simply add the information obtained in RV to that reported in OB-RV.

We remind that our choice not to alternate the two conditions, derived from the hypothesis that information obtained in OB-RV – which we believed to be more favorable – could be used in the RV if it was used afterwards.

Furthermore, this finding also suggests that the participants were not influenced by an expectation of OB-RV being the more favorable, with a consequent reduction of effort and quality of performance during the RV.

However, in the hindsight, a better experimental design is to use different targets in the RV and OB-RV conditions within each session. For example, session 1: target A for the RV condition and target B for the OB-RV; session 2 (after one week): target A for the OB-RV condition and target B for the RV condition. This experimental design variant, doesn't exclude the possibility that participants can remember the information obtained the week before, but it increases the possibility to forget it.

4.1 Possible sources of fraud

The possibility of the participants acquiring the relevant information through conventional means can be excluded. Indeed, apart from there being no doubt about their integrity from an ethical point of view, they could not have known the target in advance of the experiment and each participant did not know about the others, thus ruling out any information exchange.

The only real potential source of fraud or influence could have been the hypnotist, who knew about the target before the participants did and could have given them information during the sessions, possibly favoring OB-RV. Other than the fact that the hypnotist's professional integrity is beyond question, many of the target's details were not available on the internet and could only have been obtained by actually visiting the sites or by access to the photos used by the judges, but which were, however, taken after the experiment had ended.

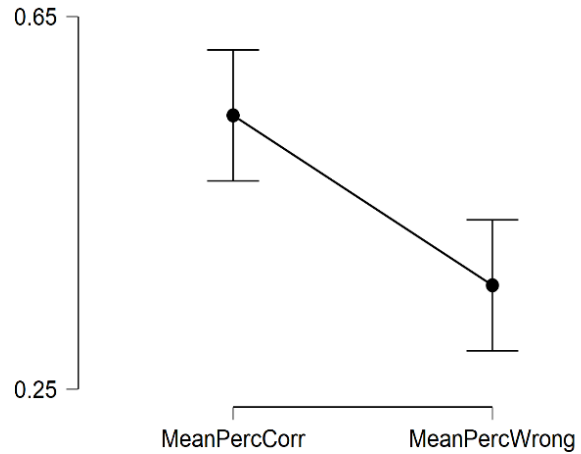

Figure 3: Means and 95% confidence intervals related to the comparison between the percentages of correct and wrong information in the RV condition

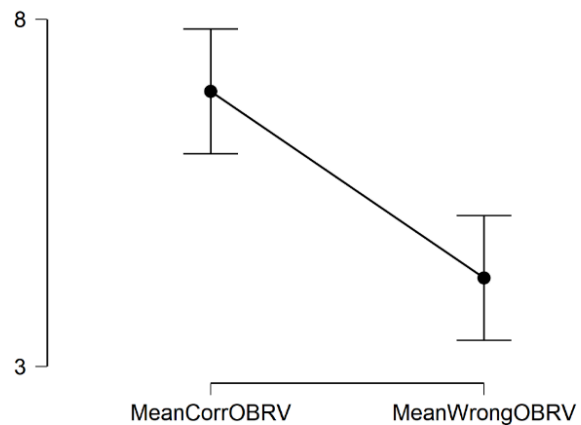

Figure 4: Means and 95% confidence intervals related to the comparison between the number of correct and wrong information in the OB-RV condition

Figure 5: Means and 95% confidence intervals related to the comparison between the percentages of correct and wrong information in the OB-RV condition

With respect to the judges, even though one is a co-au-

thor (PT), the other judge was totally unaware of what type of experiment this was. Furthermore, as already stated, all photos and information provided by the participants are freely available at <https://doi.org/10.6084/m9.figshare.12192474.v3> for independent verification.

5 Conclusions

Despite its limitations, this work indicates that it's possible to use the OB state of consciousness to obtain information from a distance in a way that supports the well-known RV techniques.

The efficacy of these procedures is sufficient for practical applications, obviously using qualified participants. For example, as it results from the total number of different information gathered by the four participants, it is possible to obtain a large number of details of the same target for its better identification.

Conflict of Interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Author Contributions

LP and PT devised the study. EP and LP managed the data collection. AB contributed to data scoring. LP and PT wrote the paper. All authors supervised the final version.

Funding

This study was carried out without funds from academic or not academic institutions.

Acknowledgments

We thank Cinzia Evangelista for English translation and revision and Stephan Schwartz for comments and suggestions. We also thank our participants for their voluntary and motivated participation.

Contribution to the field statement

This study demonstrates the possibility to use the Out-of-Body state of consciousness induced by hypnotic inductions, for practical purposes.
